NOAA-20 VIIRS Enterprise Volcanic Ash (VA) Provisional Maturity

November 27, 2018

VIIRS Volcanic Ash Team
Michael Pavolonis (STAR), Justin Sieglaff (CIMSS), Jason Brunner (CIMSS)
Outline

• Description
• Status in NDE
• SDR Issues
• Evaluation
• Provisional Maturity Conclusions
• Path Forward to Full Validation Maturity
• Future Plans

Enterprise Volcanic Ash Review
• The fundamental outputs of the VA are the ash cloud top height and ash mass loading products. Ash detection confidence can be found in the quality flag (QF).

• The ash cloud top height provides the height (km; above mean sea level) of the highest ash cloud layer.

• The ash mass loading is the column integrated total mass of ash in tons/km² (numerically equivalent to g/m²)

• Ash detection confidence: 0: high confidence; 1: moderate confidence; 2: low confidence; 3: very low confidence; 4: ash likely not present
VA Channels

- VA uses the following channels
  - M14
  - M15
  - M16

Notes:
1. Accuracy and precision requirements only apply to actual pixels that contain volcanic ash as the highest cloud layer
Our Specific Evaluation Methodology applied here:

1. Manual analysis of ash detection
2. Advection vs. ash height and loading EDRs
3. S-NPP vs NOAA-20 NDE comparisons

We have chosen volcanic eruptions for validation that the following conditions:

1. Volcanic ash is the highest cloud layer
2. Sufficient vertical wind shear for wind-height analysis and representative radiosonde (for wind-height cases)
3. Sufficient pixel count (many eruptions occupy an extremely small number of pixels and suffer from sub-pixel effects)

Thus far, there have been no coincident CALIPSO/NOAA-20 overpasses of volcanic ash
Identifying Ash Contaminated VIIRS Pixels
NOAA-20 Volcanic Ash Cases

• 9 volcanic ash cases were identified and analyzed, totaling over 5,000 NOAA-20 VIIRS M-band pixels

• Ash clouds from the following volcanoes were included:
  • 1 Popocatepetl (Mexico)
  • 2 Dukono (Indonesia)
  • 3 Sabancaya (Peru)
  • 2 Krakatau (Indonesia)
  • 1 Merapi (Indonesia)

• Land and water pixels are well represented
A web-based tool allows us to extract ash contaminated pixels using manual analysis of false color imagery.
Ash Detection: “a needle in a haystack”
The most commonly occurring ash clouds encompass 1000 pixels or less at a given time (see bar chart to the left).

On a typical day there will be 1000-10,000 ash contaminated VIIRS M-band pixels out of the ~2.5 billion M-band pixels collected each day.

Thus, ash comprises fewer than 0.0004% of VIIRS M-band pixels.
Assessment of Volcanic Ash Detection Flag
Ash Detection Assessment

- Ash clouds encompasses all ash detection categories (simple filtering by confidence is generally not effective)
The ash detection algorithm was not designed for advanced applications (e.g. alerting and dispersion modeling) due to lack of requirements and technical challenges.

Ash detection skill is computed using very low confidence, low confidence, moderate confidence, and high confidence pixels.
When EDR data are available, NOAA-20 has only observed minor ash emissions, so the probability of the pixel being flagged as very low confidence or higher is less than it would be with a more significant event.
Validation of Ash Cloud Height and Loading
Advection Analysis

As outlined in validation plan, given rare CALIPSO observations of volcanic ash co-located with NOAA-20, alternative validation methods are necessary to compliment any CALIOP/NOAA-20 analysis (currently no CALIOP/NOAA-20 ash matchups exist).

• Detection: manual analysis using RGB imagery loops. Used to assess detection and constrain height and mass loading validation statistics.

• Height: Use false color image movies (from GOES-16 and Himawari-8) to extract ash cloud motion (speed and direction). Use radiosondes to assign the satellite derived motion a height range (only cases where vertical shear is sufficient to constrain height to a ~1 km layer were used)

• Mass Loading: Satellite-derived mass loading is a strong function of the assigned cloud height. Thus, the cloud motion derived height range can be used to compute a highly representative range of “truth” mass loading.
Advection Analysis

Motion from Himawari-8 loop: 14 knots @ 65 degrees

Most of the VIIRS ash height EDR is in the 2-3 km range, consistent with the movement of the plume
Advection Analysis - Height

Mean Difference (accuracy): -1.25 km (within 3 km spec)
Advection Analysis - Height

Mean Difference (accuracy): -2.00 km (within 3 km spec)
Median Difference (accuracy): 0.57 g/m² (within 2 g/m² spec)
Interquartile range (precision): 1.15 g/m² (within 2.5 g/m² spec)
Advection Analysis - Loading

Median Difference (accuracy): 0.71 g/m² (within 2 g/m² spec)
Interquartile range (precision): 1.32 g/m² (within 2.5 g/m² spec)
S-NPP and NOAA-20 Comparisons
S-NPP vs NOAA-20 NDE Comparisons

• S-NPP and NOAA-20 orbits are separated by approximately 50 minutes

• 7 cases were chosen for comparisons where both datasets were available and not at the extreme limb of the imager

• Results should be consistent, but not identical due to actual changes in cloud properties and viewing angle differences between S-NPP and NOAA-20
S-NPP vs NOAA-20 NDE Comparison Bulk Stats

NOAA–20 and S–NPP Ash Height

Relative Frequency

Ash Height [km]

NOAA–20 Mean Height: 3.57 km
SNPP Mean Height: 3.17 km
N–20 Height Stddev: 1.12 km
SNPP Height Stddev: 0.92 km
NOAA–20 and S–NPP Ash Mass Loading

NOAA–20 Mean ML: 2.69 tons/km²
SNPP Mean ML: 2.64 tons/km²
NOAA–20 ML Stddev: 2.92 tons/km²
SNPP NL Stddev: 1.30 tons/km²
Provisional Maturity Conclusions

- An advection based validation analysis and comparisons to S-NPP indicate that the NOAA-20 volcanic ash products meet the accuracy specifications

- The Volcanic Ash Team recommends Provisional Maturity at this time
Pathway to Full Validation

- Additional volcanic eruptions will be used to increase the advection based validation analysis

- NOAA-20 vs. S-NPP comparisons will continue

- Any NOAA-20 and CALIOP coincident volcanic ash observations will be compared, should they occur.
Currently outstanding issues, unless fixed by handover, may prevent declaration of Full Validation Maturity:

- Lack of CALIOP validation data (Low)
  - CALIOP observations of volcanic ash coincident with NOAA-20 have been elusive. We plan to continue to leverage advection based validation and compare S-NPP and NOAA-20 products.

- NDE processing issues (Low)
  - I&T string feed of volcanic ash data files has become considerably more stable during Fall 2018 and processing issues are now only considered low risk.

- Situational performance issues (Low)
  - Every volcanic cloud is different; a larger eruption would enhance validation
Future Outlook (2020 and beyond)

- The VIIRS volcanic ash EDR was introduced to ensure continuity with GOES-R product requirements.
- The Enterprise Algorithm is very similar to the GOES-R baseline algorithm, which was the first automated algorithm of its kind when it was first developed in 2007-2010.
- Since 2010, far more sophisticated algorithms have been developed within the VOLcanic Cloud Analysis Toolkit (VOLCAT).
- VOLCAT is a stand-alone multi-sensor application that not only addresses the GOES-R and JPSS ash product requirements, but also introduces new capabilities such as eruption alerting.
- We continue to seek an R2O path for VOLCAT that overcomes issues associated with mission stove piping and can accommodate its unique processing requirements. VOLCAT, as is, can be implemented into operations, as the Japanese Meteorological Agency, the Australian Bureau of Meteorology, and the New Zealand Met Service have successfully transitioned VOLCAT to operations.
