## Characterization

Comparison with CRTM simulations

Clear sky over tropical and sub-tropical oceans (30N – 30S)

Three cloud screening approaches

- AMSU L2 cloud products

- PATMOS-x (AVHRR) cloud probability

- ERA Interim cloud probability

Stratification with SST, PW and wind speed (**Emphasize of this presentation**)

Yearly data: N15 – 2000, 2004, 2008

- N16 – 2008

- N18 – 2008 (\*)

- MetOp-A – 2008

## Possible Causes

- Antenna pointing angle error

- Bias in polarization vector orientation

- Sidelobe effects and other hardware configuration problem

- Asymmetric atmosphere and surface

## Correction (next step)

- Integrate the results from geolocation correction and stratification results

- Correct pointing angle error and bias in polarization vector orientation

# Literature Review

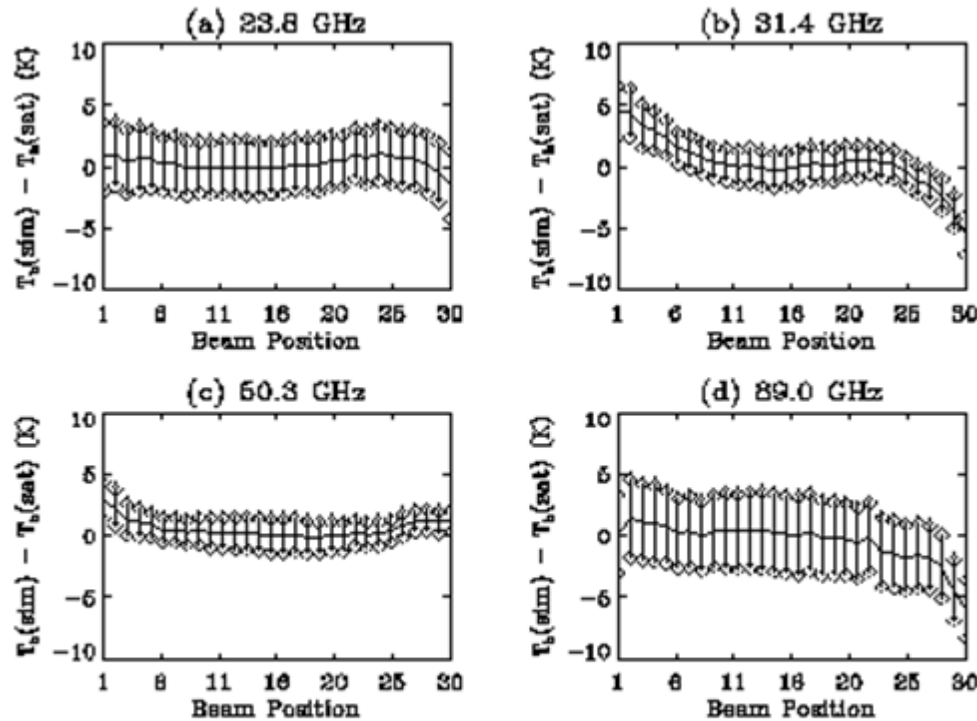

Figure 1. Mean biases of simulated brightness temperatures from observed temperatures versus beam positions under clear atmosphere over oceans at (a) 23.8 GHz, (b) 31.4 GHz, (3) 50.3 GHz, and (d) 89 GHz. Note that beam positions 1–30 correspond to the ranging of the scan angle of  $-47.85^{\circ}$ – $47.85^{\circ}$  with an increment of  $3.3^{\circ}$ . The vertical bars show the standard deviation of the biases corresponding to each beam position.

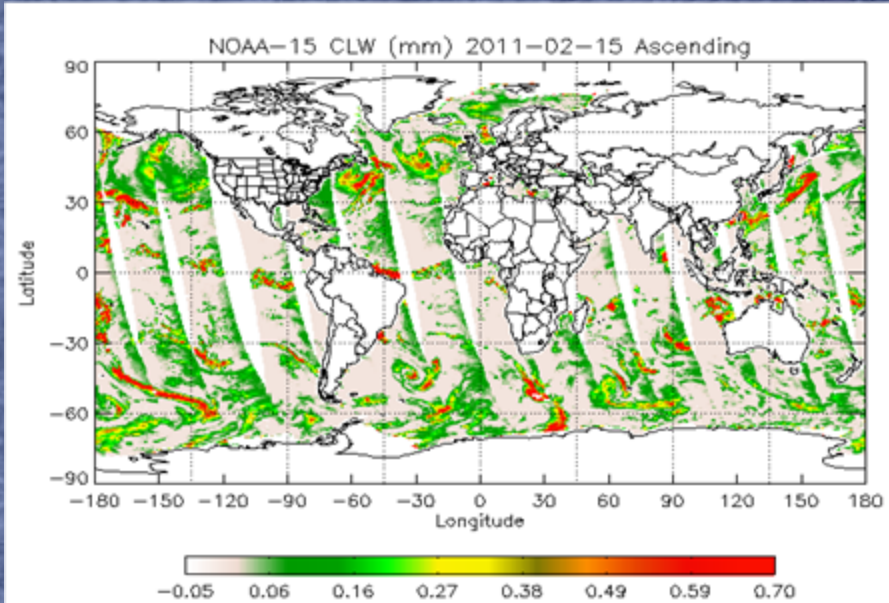

First addressed in Weng et al. (2000) and Weng et al. (2003)

Attribute to Polarization misalignment or Antenna pointing angle error

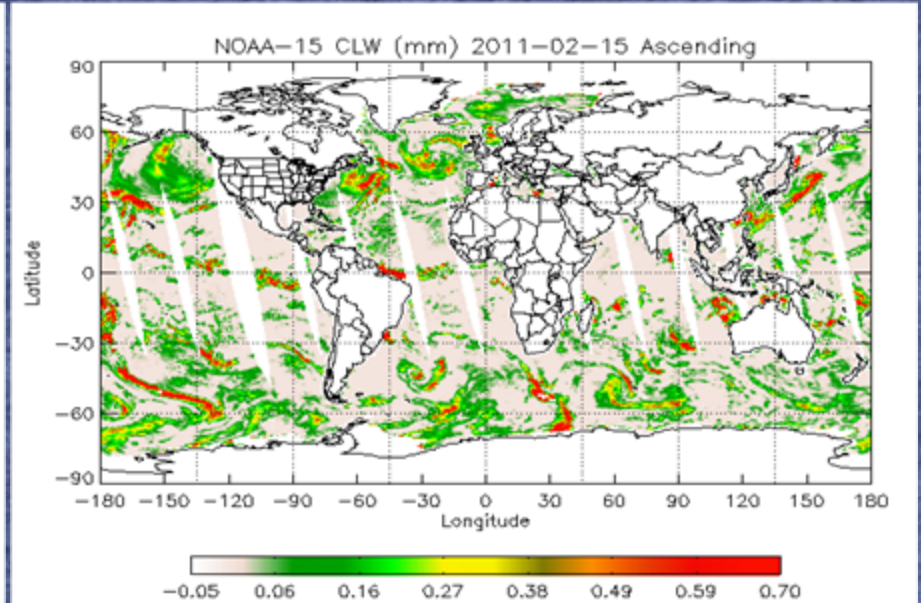

- $\theta$  – Antenna Reflector Normal Angle
- $\psi$  – Polarization Alignment Angle
- $\varphi$  – Sensor Scan Angle

$$I = A^2(\theta, \psi, \varphi) I_h + B^2(\theta, \psi, \varphi) I_v,$$

## Advantage of Using CRTM

1. Quantify both symmetric bias and asymmetric bias without introducing much extra error
2. Direct link between environment variables and radiance / brightness temperature  
Make it possible for stratification
3. Essential component in polarization related calculation
4. Essential component in double difference technique

# Average 2010 Vicarious Cold Reference vs. SST Diurnal Variability

## Conclusion

1. There is no much difference between ascending and descending nodes regarding to asymmetry  
But number of observation in descending node is almost half as that of ascending node  
The difference of number of observation mostly arise from cloud screening
2. The asymmetry is quite sensitive to combined physical conditions  
This may indicate environmental condition also have impacts on asymmetry  
Uncertainties might also arise from ERA-Interim data and CRTM
3. 31.4 GHz and 50.3 GHz asymmetries are not sensitive to sea surface temperature or precipitable water  
Wind speed is the most important physical variable to impact asymmetry
4. The asymmetry is pronounced even in a specific physical condition
5. The asymmetry pattern is stable through years, but quite different among on-board satellites
6. The mean precipitable water is not even at 30 beam positions
7. Sounding channels may provide sensor pointing information
8. How to use vicarious cold reference is still a question for us
