

# *Tropospheric Emission Spectrometer: An Earth System Sounder*

**Kevin Bowman, John Worden**

Jet Propulsion Laboratory-California Institute of Technology

# Ozone: at the nexus of air quality and climate

Marion E. Lent makes her way to work as smog dims City Hall in this 1953 photo. (Los Angeles Times), courtesy P. Wennberg-Caltech

Characterization of the vertical distribution of ozone is critical to understanding its role in atmospheric chemistry and climate

# *What is an air pollutant?*

“Because greenhouse gases fit well within the Clean Air Act’s capacious definition of “air pollutant,” we hold that EPA has the statutory authority to regulate the emission of such gases from new motor vehicles.”

MASSACHUSETTS *v.* EPA

Opinion of the Court, April 2<sup>nd</sup>, 2007

Justice Stevens

- Air pollutants now include Greenhouse Gases (GHG)
- Air quality constituents, e.g., ozone and black carbon, are also GHGs

# Radiative forcing from atmospheric composition

## Radiative Forcing Components

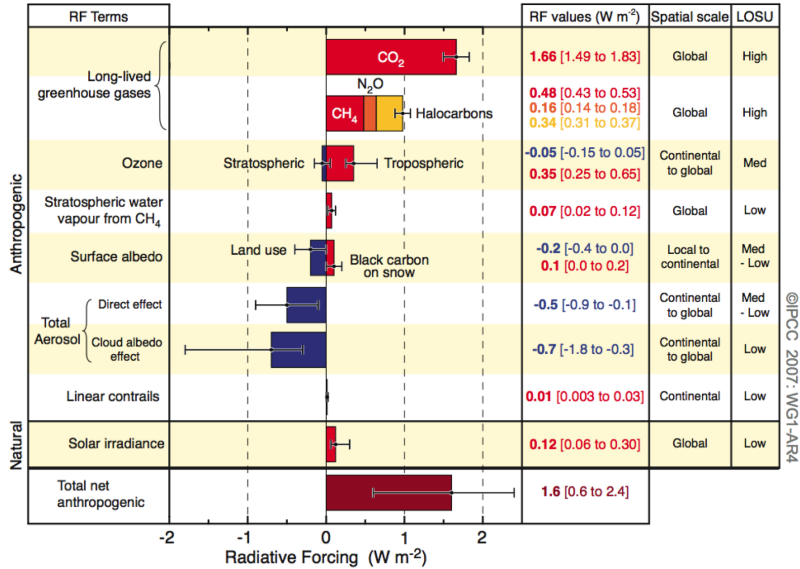

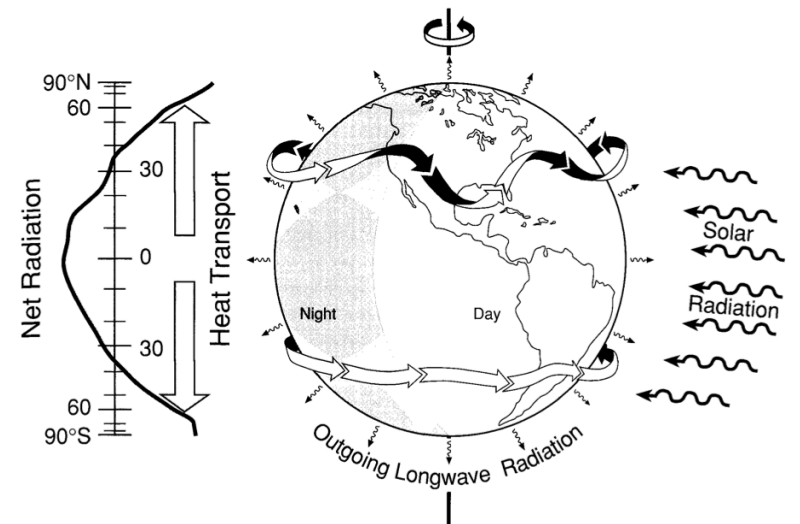

Fig. courtesy M. Mlynzcack (LaRC)

The 3 most important greenhouse gases since the preindustrial are carbon dioxide, methane, and ozone

Anthropogenic perturbation to atmospheric composition have led to a radiative imbalance at the top of the atmosphere

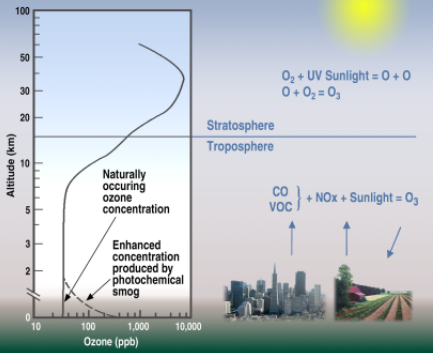

# Earth System sensitivity and response

## Chemistry

- Good (UV shield) →
- Bad (greenhouse gas) →
- Good (OH source) →
- Bad (smog) →

Net anthropogenic forcing, climate sensitivity, and response are driven by the Earth system and the coupling between its components

## Nitrogen Cycle

## Atmosphere

## Carbon Cycle

# Tropospheric Emission Spectrometer

TES, launched aboard the Aura spacecraft in 2004, is a Fourier Transform Spectrometer measures infrared spectral radiances from 3.2 to 15.4 microns.

Spectral Resolution (unapodized)	0.06 $\text{cm}^{-1}$ (nadir) 0.015 $\text{cm}^{-1}$ (hi-res)
Spectral Coverage	650 to 3050 $\text{cm}^{-1}$ (3.2 to 15.4 microns)
Global survey coverage	72 observations/orbit 16 orbits/day
Spatial Resolution	0.5 x 5 km (nadir) 2.3 x 23 km (limb)
Nadir NEDT @290K (Noise Equivalent Delta Temperature)	2B1: 1.08 K 1B2: 0.36 K 2A1: 0.36 K 1A1: 2.07 K

# What can TES observe?

TES observations

Are sensitive to

- Ozone
- Carbon monoxide
- Temperature
- Water vapor
- HDO
- Emissivity
- Effective cloud parameters
  - Cloud optical depth
  - Cloud height
- Nitric acid
- Sulfur dioxide
- ...and more

Fundamentally, TES observes *any* atmospheric or surface quantity that emits thermal radiation to space

However, information about these quantities is a function of their spectral sensitivities and natural variability

# TES observation operator: connecting measurements to assimilation

$$\| \mathbf{y} - \mathbf{F}(\mathbf{x}_a) \|_{\mathbf{S}_n}^2 + \| \mathbf{x} - \mathbf{x}_a \|_{\mathbf{S}_a}^2$$

$$\hat{\mathbf{x}} = \mathbf{x}_a + \mathbf{A}(\mathbf{x} - \mathbf{x}_a) + \mathbf{G}\mathbf{n}$$

$$\mathbf{H}_i(\bullet) = \mathbf{x}_a + \mathbf{A}_i(\bullet - \mathbf{x}_a)$$

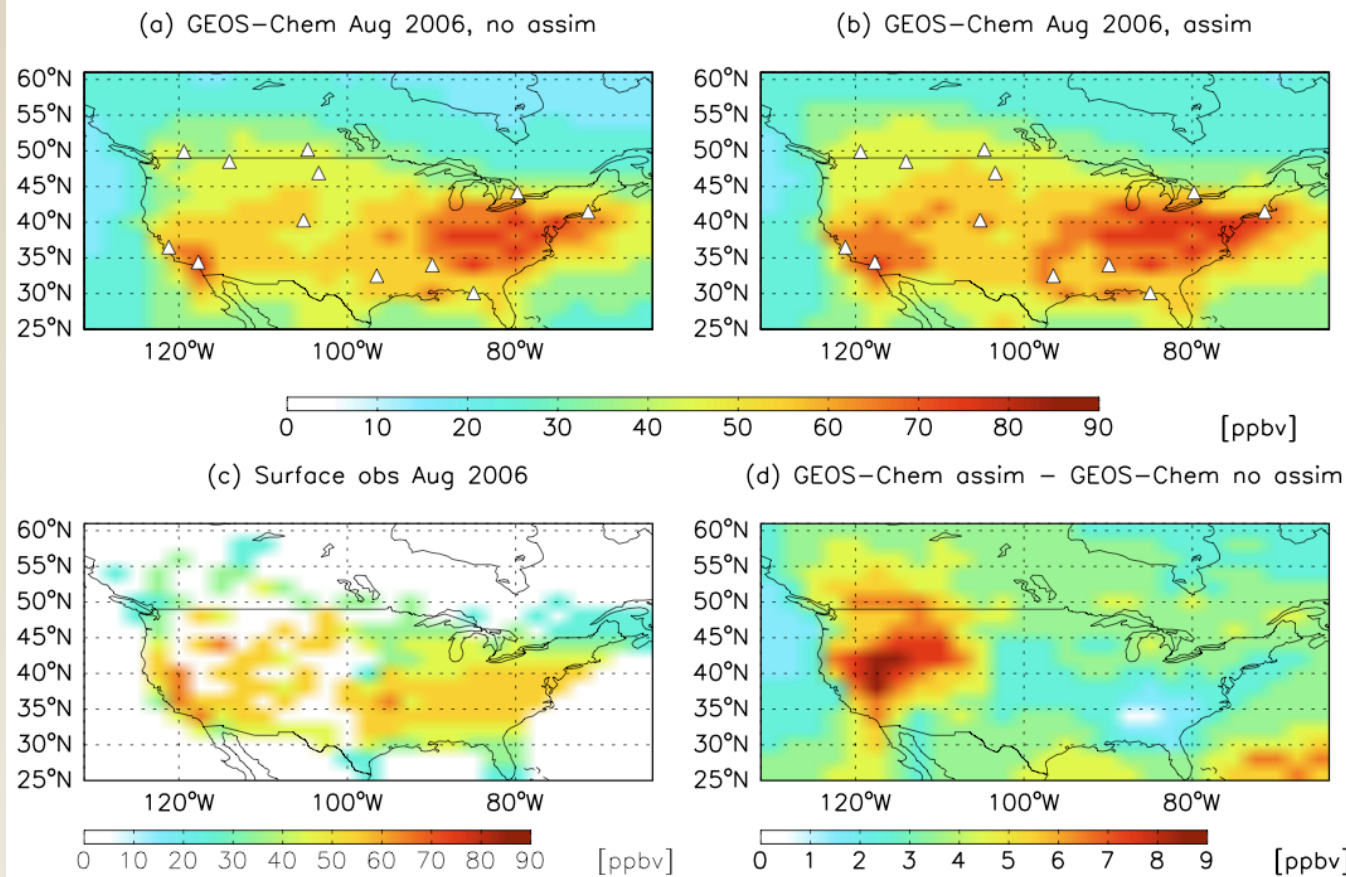

$$\sum_i \| \hat{\mathbf{x}}_i - \mathbf{H}_i(\mathbf{x}) \|_{(\mathbf{G}_i \mathbf{S}_n^i \mathbf{G}_i^T)^{-1}}^2 + \| \mathbf{x}_0 - \mathbf{x}_B \|_{\mathbf{B}^{-1}}^2$$

# Impact of distance sources on local ozone

Parrington *et al*, 2009, GRL

Assimilating TES ozone into the GEOS-Chem model increased surface ozone concentrations by up to 9ppb and free tropospheric concentrations by up to 40%.

Assimilated GEOS-Chem fields showed improved agreement with both ozone sonde measurements and western surface ozone sites

# TES instantaneous longwave radiative kernels

Clear sky

Total sky

Clear-sky tropo. IRF Kernels [ $\text{mW}/\text{m}^2/\text{ppbv}$ ]-Aug 2006

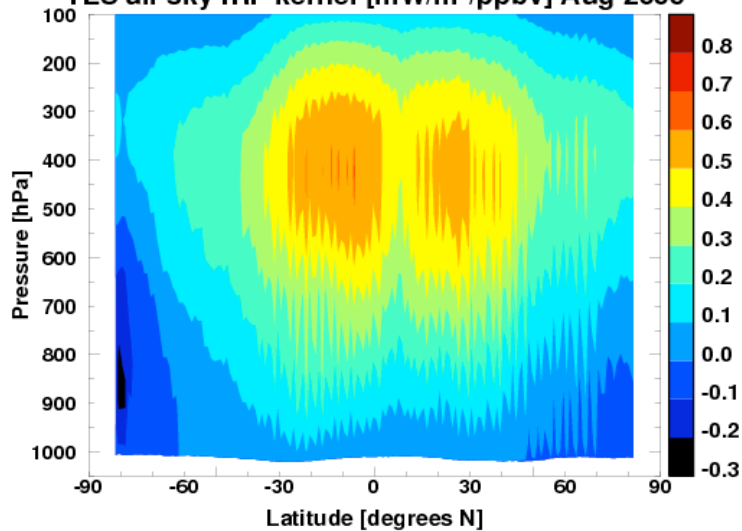

All-sky tropo. IRF Kernels [ $\text{mW}/\text{m}^2/\text{ppbv}$ ]-Aug 2006

TES clear-sky IRF kernel [ $\text{mWm}^{-2}$ ] Aug 2006

TES all-sky IRF kernel [ $\text{mW}/\text{m}^2/\text{ppbv}$ ] Aug 2006

# Direction observational constraints on ozone radiative forcing

Aghedo *et al*, 2010

Zonal-mean ozone and models' bias [ppbv]

All-sky zonal mean instantaneous radiative forcing and models' bias [milli-Watts/m<sup>2</sup>]

All-sky instantaneous radiative forcing and models' bias [Watts/m<sup>2</sup>]

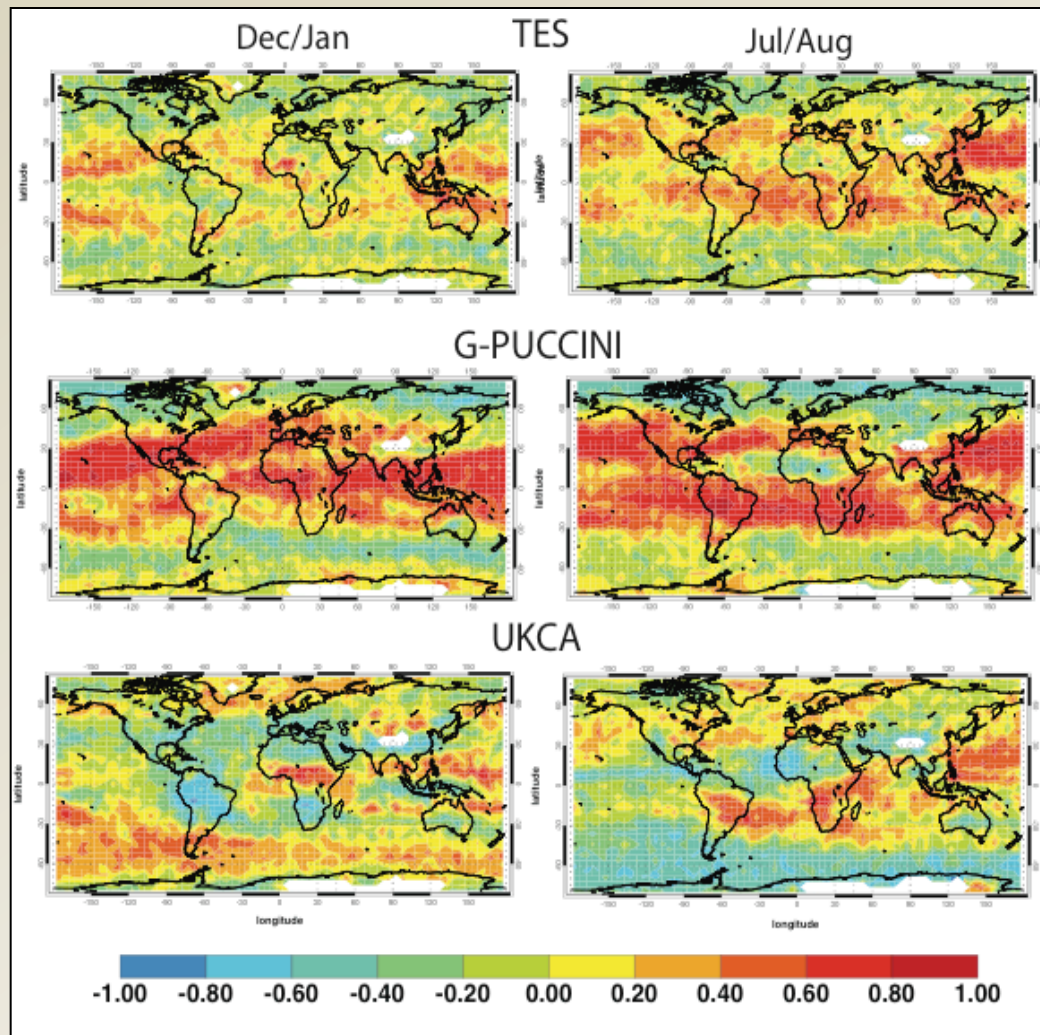

**Problem:** Tropospheric ozone is the third most important gas in terms of climate radiative forcing and this radiative forcing is highly uncertain because the vertical and horizontal distribution of ozone has significant uncertainties.

**Results:** For August 2006, TES data quantifies a zonal-average bias of about -30 to +40 mWatts/m<sup>2</sup> and the regional bias of about -40 mW/m<sup>2</sup> to 70 mW/m<sup>2</sup> in the radiative effect of tropospheric ozone predicted by four state-of-the-art chemistry models.

**Significance:** Uncertainty in the radiative forcing of tropospheric ozone is largest in the tropical and extra-tropical middle-to-upper troposphere.

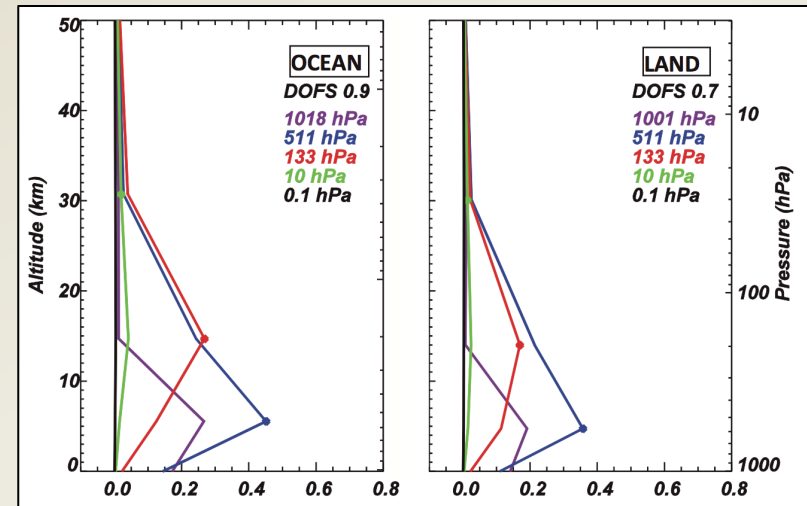

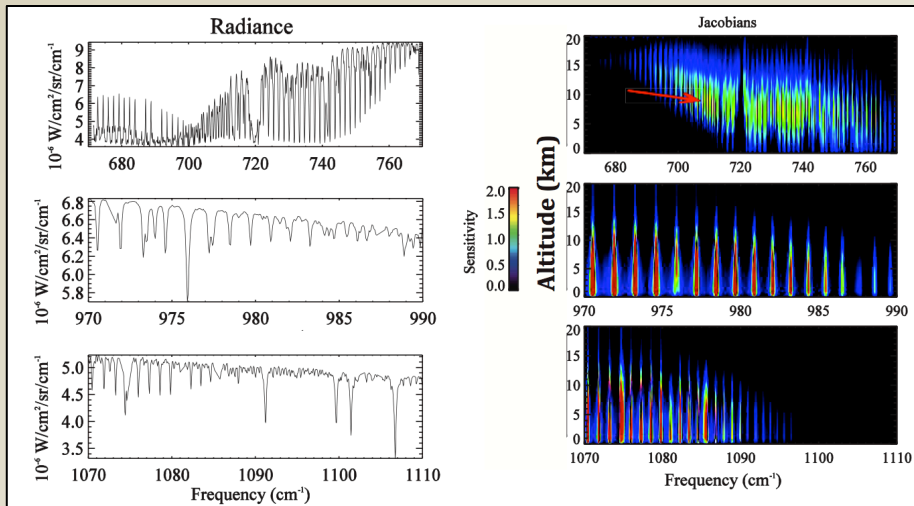

# CO-Ozone constraints on chemistry-climate models

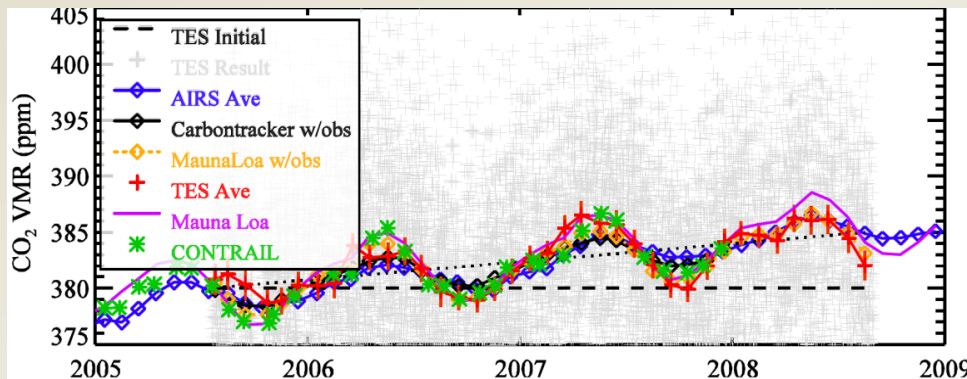

- The correlation of ozone and CO is an important tool to distinguish between combustion and background ozone.
- TES CO:O<sub>3</sub> correlations (2005-2009) have been compared to two state-of-the-art chemistry climate models:
  - NASA GISS-PUCCINI
  - UK Chemistry Aerosol Model (UKCA)
- Correlation patterns remarkably different between TES, G-PUCCINI and UKCA
  - Suggest relative balance of model natural and anthropogenic sources need to be re-examined.

# TES tropospheric CO<sub>2</sub>

Use of radiances around 10 $\mu$ m provide lower tropospheric sensitivity

Kulawik *et al*, 2010, ACP

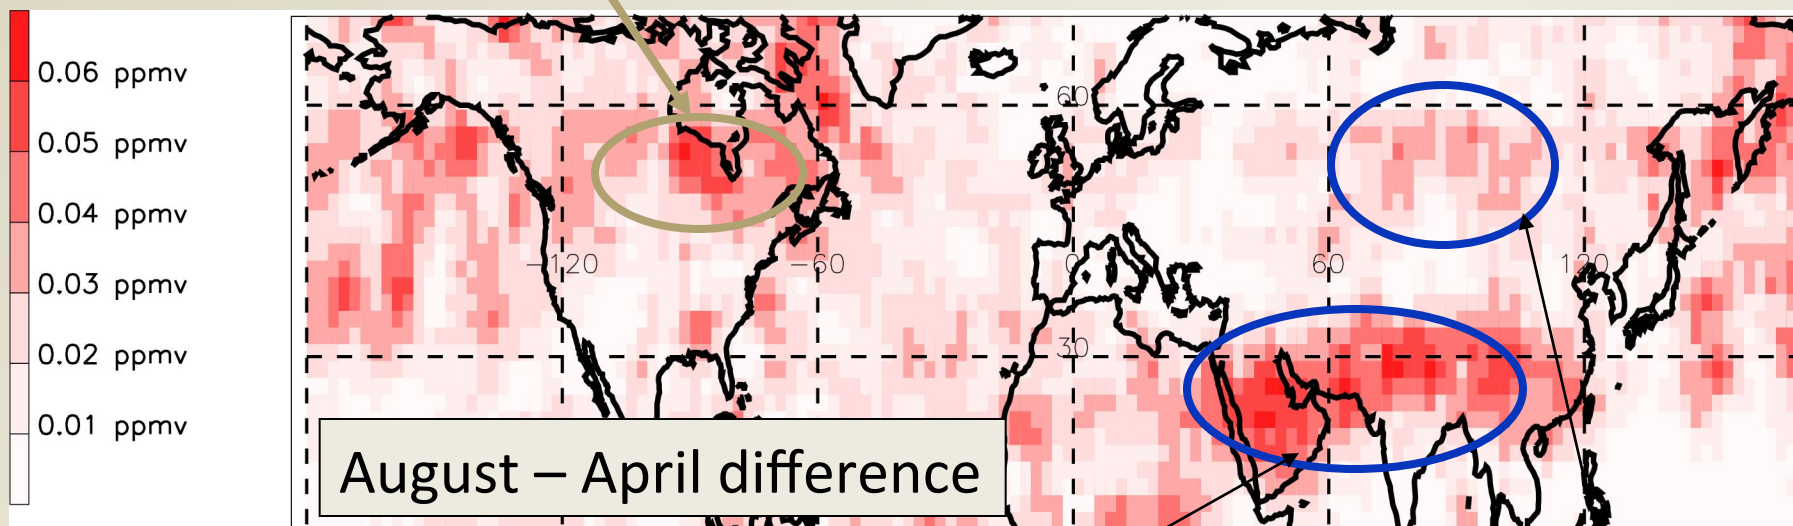

Comparisons with the HIPPO aircraft show bias from -0.6 to 0.2 ppm and correlations between 0.5 to 0.8

R. Nassar will discuss application of TES CO<sub>2</sub> to global emissions estimates

# Seasonal Differences in TES CH<sub>4</sub> (2005-2008 averages)

Hudson Bay Lowlands

Rice paddies  
(+monsoon transport)  
[Xiong et al., ACP, 2009]

Siberian wetlands

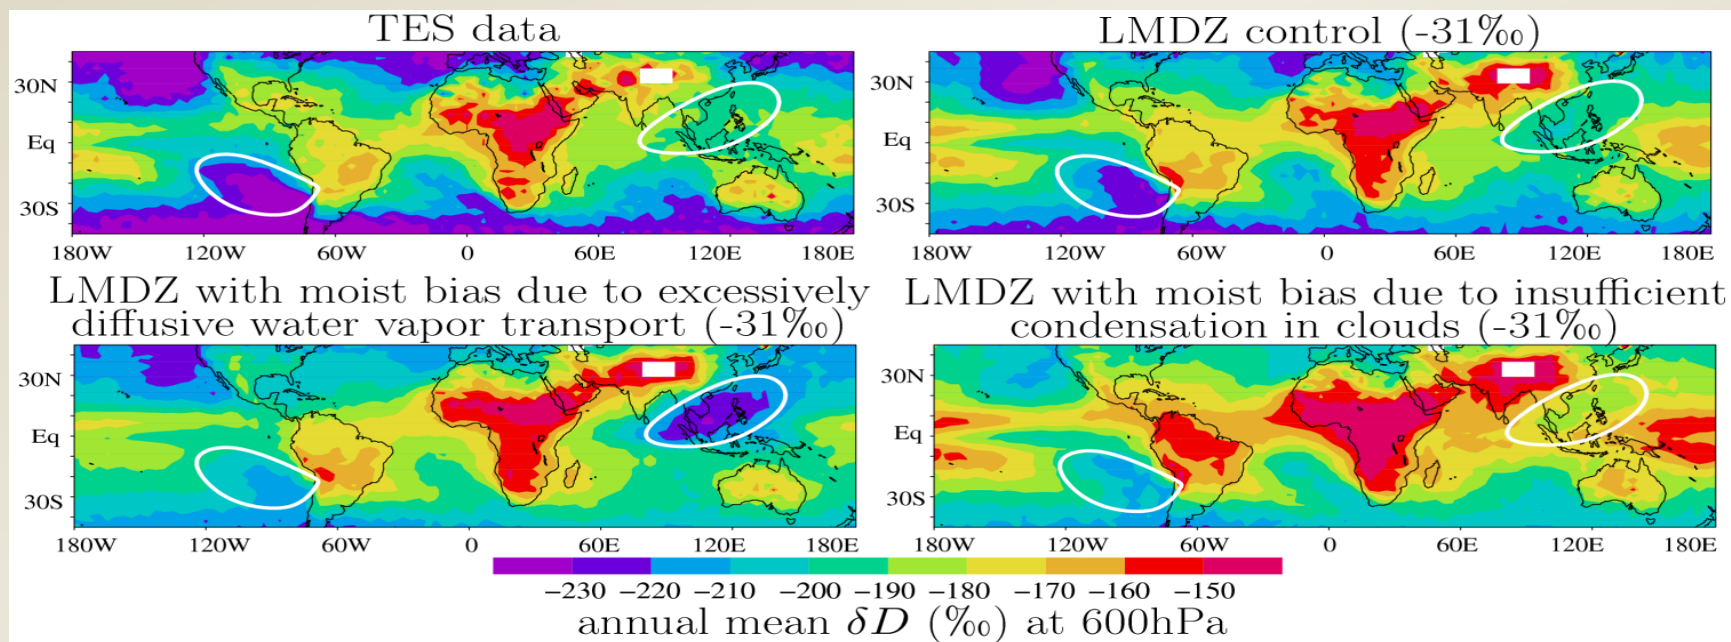

**Emissions contribute to the seasonal signal.  
Application of TES CH<sub>4</sub> to flux estimates is underway.**

# Evaluating the representation of moist processes in climate models using water vapor isotope measurements

Most climate models present a moist bias in the mid and upper troposphere: what are the processes whose representation needs improvement?

Approach: sensitivity tests with the LMDZ atmospheric model, model-data comparisons

Result: Each reason for a moist bias has a distinct isotopic signature

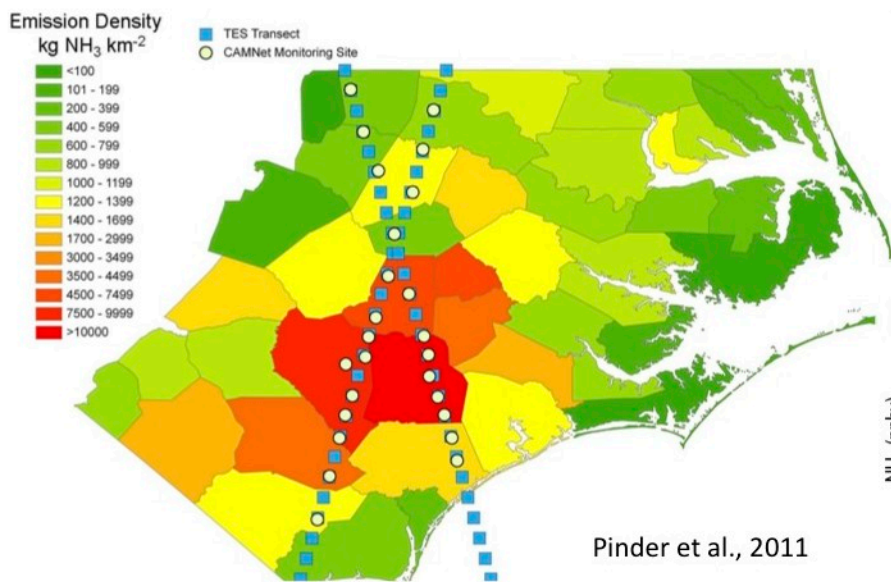

**Conclusion:** Water vapor isotope measurements can be used as observable diagnostics to understand the reason for the moist bias in atmospheric models. Applying such diagnostics to 7 atmospheric models shows that excessively diffusive water vapor transport is the most frequent reason for the moist bias.

# Observational constraints on ammonia sources

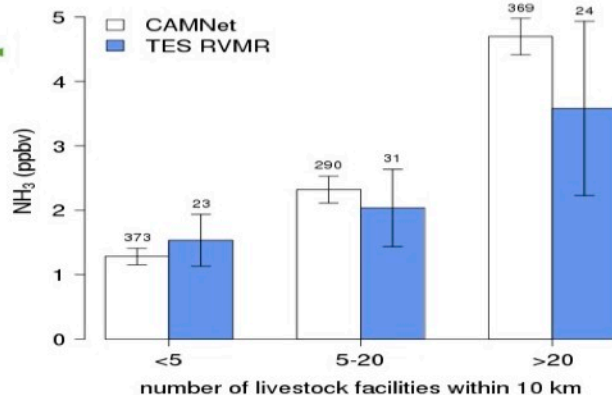

EPA ammonia surface network constructed along TES track in North Carolina show correlations in seasonal dependence and source density between satellite and ground measurements

## Seasonal dependence

## Dependence on source density

# *Conclusions*

- ❖ The TES instrument, launched aboard Aura in 2004, continues to take observations of atmospheric constituents that enable a greater understanding of atmospheric chemistry and its interactions with climate
- ❖ However, the suite of measurements possible from IR hyperspectral sounders such as TES provide insight into parts of the Earth System and their coupling.
- ❖ Future hyperspectral sounders should be designed to be the pillars of the modern Earth Observing System and the glue that connects other observations together.
